X-RAY ANTHROPOMETRY TRANSFORMATION PROGRAM

FOR THE HEWLETT-PACKARD 9000/550 COMPUTER

---

1. INTRODUCTION

The Naval Biodynamics Laboratory (NAVBIODYNLAB), located in New Orleans, Louisiana, is a research facility under the cognizance of the Naval Medical Research and Development Command. It is the only Navy laboratory conducting biomedical research on the effects of mechanical forces (motion and impact) encountered by Navy personnel. Among its goals are the establishment of human tolerance limits and the development of appropriate methods of avoiding and treating the deleterious effects of such forces. Ongoing research programs at the laboratory acquire sensor and photographic impact acceleration data from acceleration sled runs.

To analyze this data, certain anthropometric information about each subject is necessary: the locations of the head and the first thoracic vertebral body (T-1) instrumentation origins relative to the corresponding anatomical origins, as well as transformation matrices from the instrument to the anatomical coordinate systems.

A stereoradiographic technique, in which two simultaneous X-ray exposures of an instrumented subject are prepared and analyzed, is used to measure the geometrical relationships between subject mounted-instrumentation and subject anatomy. This yields a complete six-parameter statement of the position and orientation of the instrument package relative to a coordinate system fixed in the subject's bony anatomy. In the anatomical coordinate system, the mounted instrumentation is assumed to be rigidly fixed. If the geometrical relationship of these systems is known, then the transformation from one system to the other is a matter of rigid body mechanics.

Stereoradiographic techniques have been devised at the Naval Biodynamics Laboratory to measure the geometrical relationships between subject-mounted instrumentation and subject anatomy. Measurements for instrumentation mounts are made at the head and T-1.

Packages consisting of photographic targets and accelerometers that are fixed to a rigid T-shaped plate are attached to human and human analog subjects by means of an intermediary anatomical mount. These mounts are prepared so that one surface provides a rigid and highly repeatable mooring for the instrumentation packages, while another is custom molded to fit the subject's dental surfaces or bony protuberances of the spine or pelvis. The transformation from anatomical to instrumentation coordinates is governed by these anatomical mounts, with a single transformation uniquely associated with each.

Quantization of these transformations is performed radiographically. The subject is X-rayed while wearing lead markers on externally accessible anatomical features. Also worn are anatomical mounts equipped with special Plexiglass™ T-plates, in which additional lead markers ("BBs") have been fixed at known locations. The X-ray images of these markers and of other anatomical features establish the laboratory reference position of the test subject and the orientation of the instrumentation and anatomical coordinate systems. This information is used to convert anatomical to instrumentation data.

Two groups of anatomical coordinates are presently used in the work conducted at NAVBIODYNLAB. One is located in the bony anatomy of the head, the other in the first thoracic vertebral body (T-1). The head coordinate system is defined by the positions of the two auditory meatus and the notches on the inferior orbital ridges. Its origin is the midpoint of the line joining the auditory meatus. The X axis is positive from the origin through the midpoint of the line connecting the orbital notches. The X-Y plane contains the X axis and the midpoints of the lines from the left orbital notch to the left auditory meatus and from the right orbital notch to the right auditory meatus. The Z axis is positive through the top of the skull. The T-1 coordinate system is also based on four points: the posterior tip of the posterior spinous process, the anterior-superior corner of the vertebral body, and the superior corners of the right and left articular facets. Unfortunately, most of these points are not directly accessible for marking and are visible only in certain X-ray projections.

Therefore, the suprasternal notch, an externally accessible site, is used to locate a system with the anterior-superior corner at T-1, with the X axis going through the posterior tip of the posterior spinous process and positive anteriorly, and with the Y axis parallel to the line connecting the two articular facets and positive left. The Z axis is positive up.

Since the radiologic equipment used at NAVBIODYNLAB is primarily intended for diagnostic use rather than for stereometric measurement, there is no direct means of obtaining a precise statement of the system geometry necessary for this application. Therefore, stereoradiographs of a special calibration device are prepared. This device consists of thirteen lead markers set at known positions in a radiolucent Plexiglas™ prism. The prism is placed so that at least eight of the markers will be visible in each of the two X-ray exposures. The body coordinates of this prism as it is radiographed become the arbitrary laboratory reference frame. Two X-rays are taken, an anterior-posterior and a lateral projection. Markers placed on the auditory meatus and the notches of the inferior orbital ridges, as well as those in the Plexiglas™ T-plate, are clearly visible in them. The positions of these images in each of the projections can then be made to yield their lab-oriented positions, which will in turn yield the orientations and lab-oriented positions of the anatomical and instrumentation coordinates, and finally the transformation from one to the other.

The anterior-posterior and lateral X-rays are also used to quantize the T-1 instrumentation coordinate data. Markers placed on the suprasternal notch and over the T-1 posterior spinous process, as well as those in the plexiglass T-plate, are clearly visible in each X-ray. In addition, the superior corners of the right and left articular facets are visible in the anterior-posterior X-rays, and the anterior-superior corner and the superior and inferior corners of the posterior spinous process are visible in the lateral ones.

After X-rays have been taken and developed, they are examined to determine that all the various markers and anatomical features are visible. The person overseeing radiological operations locates and marks the various anatomical landmarks for digitization. In digitization, the position of each marker and landmark is measured and compared to the orientation information. Digitized positions are subjected to computational procedures to determine, first, the geometrical layout of the radiologic equipment, and then the geometry relating the mounts to the anatomy. The computation is essentially a least squares iteration.

2. FUNCTION

The following program and subroutines are used:

MXRAY:	Main program, which allows operator to select major options.
AXEB:	Inverts a matrix.
CDNTPT:	Calculates and prints transformation matrices.
POBKG:	Calculates the likeliest position and orientation of a rigid body of known geometry.
PXRY2:	Calculates the least-squared coordinates.
RLSWCH:	Right-left switch.
OPTION:	Compares calculations and uses switched values if indicated.
PRISM2:	Reads and reduces calibration data.
HTRANS:	Calculates the position and orientation of the head coordinates.

3. MAIN PROGRAM

3.1 MXRAY

This interactive program calculates X-ray anthropometry transformation matrices. The output consists of a printout and a data file containing the "Instrumentation vs. Anatomy" matrix, which is the input to the Anthropometry Data Base Update program. The following input is requested:

Subject Number (A6 format)
Date of X-ray (MON YR A6 format)
Julian Date of X-ray (I5 format)
Pcode (*a* for A-plate or *t* for T-plate, A1 format)
Julian Date of X-ray (day, year; I3,I2 format)
Option code "jo" and processing code "kk" (2I1 format)
- jo = 1 exercise the option (standard operation — always 1)
- jo = (any other number) option not exercised
- kk = 1 process head and neck data
- kk = 2 process head data only
- kk = 3 process neck data only
- kk = 4 process pelvic data only
- kk = 7 redo program
- kk = 9 end program

Comments for head data

Comments for neck data
Block or No block for neck data

3.2 COMPILATION

All of the subroutines needed to execute MXRAY are stored in the file 'libxrayantm.a,' which is in the users' library ('/usr/lib/'). The program was compiled with the following command:

fc mxray.f /usr/libxrayantm.a -o mxray

3.3 DATA FILES

The file 'input' should always contain the subject data to be processed. The file 'output' will always be used to store the processed data. The file 'update' will always be used to store the transformation matrices. The file 'IOupdate' is a shell procedure that updates the input file, saves the previous output, and executes the main program.

3.4 EXECUTION

The executable code is stored in the file 'mxray.' To execute the program, execute the shell procedure 'IOupdate' by typing the appropriate file names in the following form:

IOupdate newinputfilename oldoutputfilename oldupdatefilename

Assuming subject H00290 was processed, the output from program execution is in files 'output' and 'update.' The data will be saved on the next execution of 'IOupdate.' The user input would be as follows:

IOupdate input H00290.out H00290.up

The file 'input' contains data for the subject to be processed. The naming convention for the files 'oldoutputfilename' and 'oldupdatefilename' is 'subjectID.out' and 'subjectID.up,' respectively.

The program will request input, organize and coordinate calculations. To get printed results, execute the "lp" command using the file 'output.'

4. SUBROUTINE DESCRIPTIONS

4.1 AXEB

The routine AXEB inverts a matrix. The call is:

call axeb (a,n,n1,jc)

where

A = the matrix to be inverted
N = the number of rows in matrix A
N1 = the number of columns in matrix A
JC = the work array used by this routine

4.2 CDNTPT

The routine CDNTPT calculates in anatomical coordinates the vector from the instrument origin to the anatomical origin. It also generates the transformation matrix that translates a vector from the instrumentation coordinate system to the anatomical coordinate system. The call is:

call cdntpt

4.3 POBKG

The routine POBKG calculates the vector defining the instrument origin lab coordinates and also calculates the transformation matrix from the instrument to the laboratory system. The call is:

call pobkg (x,xx,ii,pp,a)

where

X = represents a two-dimensional, three-by-three array containing the best least squares coordinates of the center right, and left T-plate BBs in the lab coordinate system as calculated in subroutine PXRY2
XX = a two-dimensional, three-by-three array containing the location of the three instrument BBs in the instrument coordinate system
II = the number of BBs on the T-plate (normally 3)
PP = the vector defining the instrument origin in lab coordinates

A = the transformation matrix (3 × 3) that takes a vector from the instrument coordinate system and translates it into the lab coordinate system

4.4 PXRY2

The routine PXRY2 calculates the best least square coordinates in the lab coordinate system. The call is:

call pxry2 (x,a,r,xr)

where

X = the best least squares estimate of BBs in lab coordinates
A = the measured X-ray coordinates of the nth BB
R = the sum of the square of the error between the measured and the projected X-ray coordinates
XR = the X-ray coordinates obtained by projection of the calculated position of the BB onto the X-ray film planes

4.5 RLSWCH

The routine RLSWCH allows an optional right-left switch of the anterior-posterior (AP) and lateral X-ray coordinates. The call is:

call rlswch (j,k,sp)

where

J = represents the index of the right side BB on the lateral view as obtained from measurement
K = the index of the right side BB so labeled by this subroutine and has identical X-ray coordinates as the measured labeled left side BB
SP = the array containing the measured coordinates of the AP and lateral views. This array also contains the right-left/left right switch of coordinates in the last 24 elements

4.6 OPTION

The routine OPTION compares the error associated with the measured location of right and left BBs with the error associated with the right and left BBs as defined in subroutine RLSWCH. If the error is smaller for the point as labeled, the routine prints "Option Not Indicated." If the error is greater, the routine may either disregard the as-labelled calculation and use that of the switched labels (defined by subroutine RLSWCH) and print "Option Indicated and Exercised"; or, if the operator wishes, continue to use the as-labeled calculation and print "Option Indicated But Ignored." The call is:

call option (j,k,er,x,jo)

where

J = the number of the right-side BBs as obtained from lateral view measurements

K = the number of the right-side BBs as labeled by subroutine RLSWCH

ER = a one-dimensional array containing the sum of the squares of the difference between the "measured" and "calculated" AP and lateral X-ray coordinates of the BB under scrunity

X = two-dimensional, three-by-thirteen array containing the best least squares coordinates for the BB under scrutiny, as calculated in subroutine PXRY2

JO = the code that determines if an option is to be exercised, as follows:

1	— Exercise option
Any other number	— Do no exercise option

4.7 PRISM2

The routine PRISM2 reads and reduces calibration data. This subroutine establishes the lab coordinate system and calculates both the AP and lateral camera orientations and positions. The call is:

call prism2 (xop,xsp,cp)

where

XOP = the best estimate of the vector from lab to X-ray origin in X-ray coordinates

XSP = the best estimate of the vector from source origin to X-ray origin in X-ray coordinates

CP = the best estimate of the transformation matrix from lab to X-ray

4.8 HTRANS

The routine HTRANS calculates the anatomical origin of the head in lab coordinates and the transformation matrix, which takes a vector in lab coordinates and transforms it into a vector in the head anatomical coordinate system. The call is:

call htrans (x)

where

X = the array containing the lab coordinates of the four head anatomical BBs plus the three T-plate BBs plus the six coordinates obtained by performing a right-left/left-right switch of measure-defined locations of BBs from the X-ray view

5. UTILITY SUBROUTINES

Two utility subroutines are used in the X-ray transformation program and are included for completeness. A brief description of each is given in this section.

5.1 CAPS

The routine CAPS enables the 'caps' mode on the HP-2627A terminal. The call is:

call caps

5.2 CAPOFF

The routine CAPOFF disables the 'caps' mode on the HP-2627A terminal. The call is:

call capoff

 1          subroutine htrans (x)
 2    c
 3    c  subroutine htrans
 4    c
 5    c
 6    c  This subroutine calculates the anatomical origin of the head
 7    c  in lab coordinates and the transformation matrix which takes
 8    c  a vector in lab coordinates and transforms it into a vector
 9    c  in the head anatomical coordinate system.
10    c
11    c  input consist of:
12    c  x(3,13) = the lab coordinates of the 4 head anatomical bee bee's
13    c  plus t3 t-plate bee bee's plus the 6 coordinates obtained
14    c  by performing a right-left/left-right switch of measure
15    c  defined locations of bee's bee's from the x-ray view.
16    c  These are computed in subroutine pxryz by a least squares
17    c  technique.
18    c
19    c  xt(3t(3)  = created in subroutine pobkg where it was called 'pp(i)'
20    c  and  and is the vector defining the instrument origin i
21    c  lab coordinates.
22    c
23    c  at(3,3) = created in subroutine 'pobkg' where it was called 'a(3,3)'
24    c  and is the transformation matrix that takes a vector from
25    c  instrument trument into the lab coordinates system.
26    c
27    c  output consist of:
28    c  xh(i)  = (x(i,2) + x(i,1))/2 = anat origin in lab.
29    c
30    c  ah(3,3) = is the transformation matrix which takes a vector in lab
31    c  coordinates and transforms it into a vector in the head
32    c  anatomical system.

 1          subroutine prism2 (xop,xsp,cp)
 2  c
 3  c
 4  c  This subroutine establishes the lab coordinate system and
 5  c  calculates both the ap and lateral camera orientations and
 6  c  positions in the lab.
 7  c
 8  c  Inputs are all initial guesses
 9  c  xo = vector from lab to x-ray origin in x-ray coordinates
10  c
11  c  xs = vector from source origin to x-ray origin in x-ray coordinates
12  c
13  c  c = transformation matrix from [lab/xray]?
14  c
15  c  Outputs are the best estimates of the three inputs above?
16  c
17  c
18  c
19  c  Revised December 1987
20  c
21  c  The following assumptions were made:
22  c
23  c  (1) xs is the same for ap and lateral calibration and is
24  c      constant for all runs.
25  c      The value of xs: 0.0, 0.0, 150.
26  c
27  c  (2) xo is different for ap and lateral calibration but is
28  c      constant for all runs.
29  c      The values of xo are: (ap) 20., 0.0, 10.; (lat) 0.0, 0.0, 10.
30  c
31  c  (3) c is different for ap and lateral calibrations but is
32  c      constant for all runs.
33  c      The values of c are:
34  c  (ap)  (lat)
35  c              -1.0, 0.0, 0.0                          0.0, 0.0, 1.0
36  c               0.0, 0.0, 1.0                          1.0, 0.0, 0.0
37  c               0.0, 1.0, 0.0                          0.0, 1.0, 0.0
38  c

 1          subroutine pxry2 (x,a,r,xr)
 2  c
 3  c  subroutine pxryz
 4  c
 5  c
 6  c  This subroutine calculates the best least square coordinates
 7  c  in the lab (x(i),i=1,2,3) consistent with the ap & lateral x-ray
 8  c  coordinates of all bee bee's and possible right-left ambiguities
 9  c  arising from the lateral x-ray view.
10  c
11  c  input consist of:
12  c  a(2,2)  = the ap,x; ap,y; lat,x; lat,y; measured x-ray coordinates
13  c            of the ith bee bee. i=1,7 for neck monut, i=1,13 for head
14  c            mount.  Also known a sp(2,2,13) in subroutine rlswch and
15  c            as spi(4,13) in the main program.
16  c
17  c  xo(3,2) = vectors from lab to x-ray origin (ap:lat) in x-ray coord's
18  c
19  c  xs(3,2) = vector from camera origin to x-ray origin in x-ray coord's
20  c
21  c  c(3,3,2)= transformation matricces from [lab/x-ray]ap:[lab/xray]lat.
22  c
23  c  output consist of:
24  c  x(3)  = best least squares estimate of bee bee in lab coordinates
25  c
26  c  r  = sum of the square of the error between the measured
27  c       x-ray coordinates and the x-ray coordinates obtained by
28  c       projection of the best least squares position of the bee
29  c       bee onto both x-ray film planes.
30  c
31  c  r  = [ap(x,y)measured-ap(x,y)theory]**2.0 +
32  c       [lat(x,y)measured-lat(x,y)theory]
33  c
34  c  xr(2,2) = the x-ray coordinates obtained by projection of the
35  c            calculated position of the bee bee onto the x-ray film
36  c            planes. It is called xtp(4) in the main program.
37  c            It is used in the neck calculations.
38  c
39  c  bench marks of intrest consist of:
40  c  x(1)  = x(1)+det(2)/det(1) the sum of the change in the x
41  c          component of the lab coordinates of the bee bee for each
42  c          iteration for the best coordinate calculation routine.
43  c
44  c  e  = the magnitude of the change squared of x(3) above,
45  c       calculated for each iteration of the best coordinates
46  c       routine.
47  c
48  c

 1          subroutine rlswch (j,k,sp)
 2    c
 3    c  subroutine rlswch
 4    c
 5    c
 6    c  This subroutine gathers the ap and lat x-ray coordinates of the
 7    c  anatomical instrument bee bee's. It then generates additional points
 8    c  by making an alternate switch of the possible ambiguities which
 9    c  could arise when varying certain bee bee locations on the lateral
10    c  x-rays.
11    c
12    c  input and output consist of:
13    c  sp(2,2,13) = t the first 28 elements of this array contain the
14    c                  measured coordinates of the ap and lat views of the
15    c                  the subject's bee bee's, and are passed to this
16    c                  subroutine from the main program. The last 24 elements
17    c                  array are empty and will receive the right-left/left-
18    c                  right switch of coordinates performed by this
19    c                  subroutine.
20    c
21    c  j  =            the index of the right side bee bee on the lateral
22    c  view as obtained from measurement.
23    c
24    c  k  = the index of the right-side bee bee so labeled by
25    c       this subroutine and has identical x-ray coordinates
26    c       as the measured labeled left side bb. A least square
27    c       solution with accompanying error for both labeled bee
28    c       bee's in lab coordinates is determined in subroutine
29    c       pxry2. If the proper switch is set in subroutine option
30    c       the discreptences will be automatically corrected there
31    c
